Calculating Political Bias in Korean Language Models

Song Jongbeen & Song Sanghoun†

Korea University

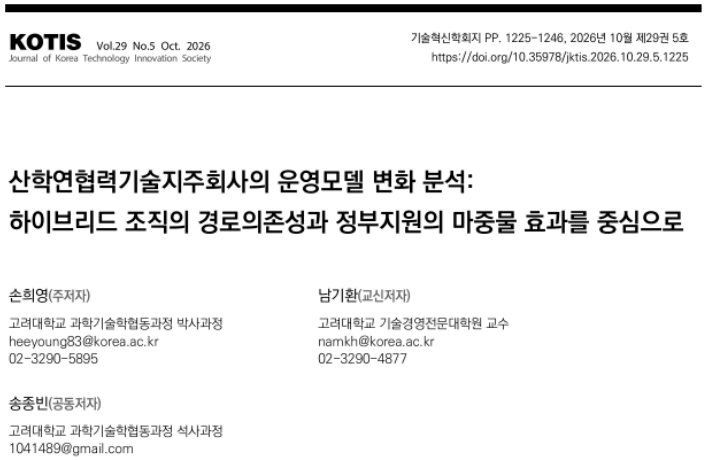

ABSTRACT

This study audits the political orientations of seven instruction-tuned Korean large language models (LLMs) amid expanding sovereign-AI deployment. Diverging from Western-centric benchmarks, we evaluate these models using three localized instruments: The Community test, the Hankr Political Compass, and the JoongAng Ilbo's 2025 Political Orientation Test. Results reveal substantial cross-model dispersion, with no model remaining entirely neutral. While economic orientations generally lean moderately left, social and cultural positions vary widely. Notably, this variation correlates more with developer type and release period than parameter size, suggesting that institutional contexts, training data, and alignment practices leave distinct political fingerprints. Ultimately, this reproducible, Korea-specific audit framework establishes a baseline for evaluating LLM political bias and informs context-sensitive alignment strategies for sovereign AI development.

How Does Generative AI Structure Risk? Algorithmic Auditing of Cultural Prototypes and Risk Judgment Factors in Large Language Models

Jongbeen Song[1]
Mikyung Chang[2]

Abstract

Large language models (LLMs) increasingly mediate risk information, yet it is unclear whether cultural and psychometric structures from human risk-perception research are reproduced in their outputs. Drawing on grid-group cultural theory, the psychometric paradigm, and the concept of outrage, we conducted a computational-psychometric algorithmic audit of seven LLMs under controlled zero-shot conditions, administering every item in two anchor orders across repeated administrations. Across 13 risk issues and nine outrage factors, the risk issue accounted for 72.5% of the variance in riskiness ratings, compared with 3.4% attributable to model identity, while lack-of-knowledge factors occupied the bottom two positions in 25 of 36 model-administration analyses (69%), with several correlations showing the direction opposite to those reported for human samples. Cultural position, by contrast, proved condition-dependent: Grid and Group indices were stable across repeated administrations (ICC(1,1) = .956 and .787), yet the low-Grid tendency shifted with item composition and cut-point choice, so attributing a cultural prototype to any single model is not warranted. We therefore propose an algorithmic-audit approach that measures the stability, condition sensitivity, and issue dependence of LLM response structures rather than assigning cultural prototypes to models.
